## AMIDINO DERIVATIVES AND THEIR USE AS THROMBIN INHIBITORS

This application is a continuation of application Ser. No. 09/509,032, filed Mar. 21, 2000, now U.S. Pat. No. 6,750, 243 the entire content of which is hereby incorporated by reference in this application.

### FIELD OF THE INVENTION

This invention relates to novel pharmaceutically useful compounds, in particular compounds that are, or are prodrugs of, competitive inhibitors of trypsin-like serine proteases, especially thrombin, their use as medicaments, pharmaceutical compositions containing them and synthetic routes to their production.

### BACKGROUND

Blood coagulation is the key process involved in both haemostasis (i.e. the prevention of blood loss from a damaged vessel) and thrombosis (i.e. the formation of a blood clot in a blood vessel, sometimes leading to vessel obstruction).

Coagulation is the result of a complex series of enzymatic reactions. One of the ultimate steps in this series of reactions is the conversion of the proenzyme prothrombin to the active enzyme thrombin.

Thrombin is known to play a central role in coagulation. It activates platelets, leading to platelet aggregation, converts fibrinogen into fibrin monomers, which polymerise spontaneously into fibrin polymers, and activates factor XIII, which in turn crosslinks the polymers to form insoluble fibrin. Furthermore, thrombin activates factor V and factor VIII leading to a "positive feedback" generation of thrombin from prothrombin.

By inhibiting the aggregation of platelets and the formation and crosslinking of fibrin, effective inhibitors of thrombin would be expected to exhibit antithrombotic activity. In addition, antithrombotic activity would be expected to be enhanced by effective inhibition of the positive feedback mechanism.

Further, it is known that administration of prodrugs of thrombin inhibitors may give rise to improvements in:

- certain pharmacokinetic properties after administration of; and
- the prevalence of certain side effects associated with, those inhibitors.

### PRIOR ART

The early development of low molecular weight inhibitors of thrombin has been described by Claesson in Blood Coagul. Fibrinol. (1994) 5, 411.

Blombäck et al (in J. Clin. Lab. Invest. 24, suppl. 107, 59, (1969)) reported thrombin inhibitors based on the amino acid sequence situated around the cleavage site for the fibrinogen A $\alpha$  chain. Of the amino acid sequences discussed, these authors suggested the tripeptide sequence Phe-Val-Arg (P9-P2-P1, hereinafter referred to as the P3-P2-P1 sequence) would be the most effective inhibitor.

Thrombin inhibitors based on dipeptidyl derivatives with an  $\alpha,\omega$ -aminoalkyl guanidine in the P1-position are known from U.S. Pat. No. 4,346,078 and International Patent Application WO 93/11152. Similar, structurally related, dipeptidyl derivatives have also been reported. For example International Patent Application WO 94/29336 discloses com-

pounds with, for example, aminomethyl benzamidines, cyclic aminoalkyl amidines and cyclic aminoalkyl guanidines in the P1-position (International Patent Application WO 97/23499 discloses prodrugs of certain of these compounds); European Patent Application 0 64S 780, discloses compounds with, for example, cyclic aminoalkyl guanidines in the P1-position.

Thrombin inhibitors based on peptidyl derivatives, also having cyclic aminoalkyl guanidines (e.g. either 3- or 4-aminomethyl-1-amidinopiperidine) in the P1-position are known from European Patent Applications 0 468 231, 0 559 046 and 0 641 779.

Thrombin inhibitors based on tripeptidyl derivatives with arginine aldehyde in the P1-position were first disclosed in European Patent Application 0 185 390.

More recently, arginine aldehyde-based peptidyl derivatives, modified in the P3-position, have been reported. For example, International Patent Application WO 93/18060 discloses hydroxy acids, European Patent Application 0 526 877 des-amino acids, and European Patent Application 0 542 525 O-methyl mandelic acids in the P3-position.

Inhibitors of serine proteases (e.g. thrombin) based on electrophilic ketones in the P1-position are also known. For example, European Patent Application 0 195 212 discloses peptidyl  $\alpha$ -keto esters and amides, European Patent Application 0 362 002 fluoroalkylamide ketones, European Patent Application 0 364 344  $\alpha,\beta,\delta$ -triketocompounds, and European Patent Application 0 530 167  $\alpha$ -alkoxy ketone derivatives of arginine in the P1-position.

Other, structurally different, inhibitors of trypsin-like serine proteases based on C-terminal boronic acid derivatives of arcyinine and isothiuronium analogues thereof are known from European Patent Application 0 293 881.

More recently, thrombin inhibitors based on peptidyl derivatives have been disclosed in European Patent Application 0 669 317 and International Patent Applications WO 95/35309, WO 95/23609, WO 96/03374, WO 96/25426, WO 96/31504, WO 97/02284, WO 97/46577, WO 96/32110, WO 98/06740, WO 97/49404 and WO 98/57932.

However, there remains a need for effective inhibitors of trypsin-like serine proteases, such as thrombin. There is a particular need for compounds which are both orally bioavailable and selective in inhibiting thrombin over other serine proteases. Compounds which exhibit competitive inhibitory activity towards thrombin would be expected to be especially useful as anticoagulants and therefore in the therapeutic treatment of thrombosis and related disorders.

Particular tautomeric forms of compounds of the invention that may be mentioned include those connected with the position of the double bond in the amidine functionality in the structural fragment B, and the position of D<sup>1</sup> and D<sup>2</sup>, when one of these does not represent H. Further, it will be appreciated by those skilled in the art that, in the structural fragment of formula IIa, the optional double bonds, may, in conjunction with certain identities of substituent D, render the ring bearing A, E and D aromatic in character.

The compounds of formula I may also contain one or more asymmetric carbon atoms and may therefore exhibit optical and/or diastereoisomerism. All diastereoisomers may be separated using conventional techniques, e.g. chromatography or fractional crystallisation. The various stereoisomers may be isolated by separation of a racemic or other mixture of the compounds using conventional, e.g. fractional crystallisation or HPLC, techniques. Alternatively the desired optical isomers may be made by reaction of the appropriate optically active starting materials under conditions which will not cause racemisation or epimerisation, or by derivatisation, for example with a homochiral acid followed by separation of the diastereomeric derivatives by conventional means (e.g. HPLC, chromatography over silica). All stereoisomers are included within the scope of the invention.

Substituents on the aromatic and/or non-aromatic, carbocyclic and/or heterocyclic ring(s) in compounds of formulae I, IV, V, VI, VII, VIII, IX, X, XI, XII, XVI, XVII, XIX, XX, XII, XXII, XXIII, XXVI, XXIX, XXX, XXXI, XXX, X XXXV, XXXV, XXXVI, XXXVII, XXXVIII, XXXIX, XL and XLI may be introduced and/or interconverted using techniques well known to those skilled in the art. For example, nitro may be reduced to amino, hydroxy may be alkylated to give alkoxy, alkoxy may be hydrolysed to hydroxy, alkenes may be hydrogenated to alkanes, halo may be hydrogenated to H, etc.

The compounds of formula I may be isolated from their reaction mixtures using conventional techniques.

It will be appreciated by those skilled in the art that in the process described above the functional groups of intermediate compounds may need to be protected by protecting groups.

Functional groups which it is desirable to protect include hydroxy, amino and carboxylic acid. Suitable protecting groups for hydroxy include trialkylsilyl or diarylalkylsilyl groups (e.g. t-butyltrimethylsilyl, t-butylphenylsilyl or trimethylsilyl) and tetrahydropyranyl. Suitable protecting groups for carboxylic acid include C<sub>1-6</sub> alkyl or benzyl esters. Suitable protecting groups for amino, amidino and guanidino include t-butyloxycarbonyl, benzyloxycarbonyl or 2-trimethylsilylethoxycarbonyl (Teoc). Amidino and guanidino nitrogens may also be protected by hydroxy or alkoxy groups, and may be either mono- or diprotected.

The protection and deprotection of functional groups may take place before or after coupling, or before or after any other reaction in the abovementioned schemes.

Protecting groups may be removed in accordance with techniques which are well known to those skilled in the art and as described hereinafter.

Persons skilled in the art will appreciate that, in order to obtain compounds of formula I in an alternative, and, on some occasions, more convenient, manner, the individual process steps mentioned hereinbefore may be performed in a different order, and/or the individual reactions may be performed at a different stage in the overall route (i.e. substituents may be added to and/or chemical transformations performed upon, different intermediates to those mentioned hereinbefore in conjunction with a particular reaction). This may negate, or render necessary, the need for protecting groups.

For example, this is particularly true in respect of the synthesis of compounds of formula I in which D<sup>1</sup> or D<sup>2</sup> (as appropriate) does not represent H. In this case, OR<sup>a</sup> and/or C(=X<sup>11</sup>)X<sup>12</sup>R<sup>b</sup> groups may be introduced at an earlier stage in the overall synthesis using the process steps described hereinbefore.

Accordingly, the order and type of chemistry involved will dictate the need, and type, of protecting groups as well as the sequence for accomplishing the synthesis.

The use of protecting groups is fully described in "Protective Groups in Organic Chemistry", edited by J W F McOmie, Plenum Press (1973), and "Protective Groups in Organic Synthesis", 2nd edition, T W Greene & P G M Wutz, Wiley-Interscience (1991).

The protected derivatives of compounds of formula I may be converted chemically to compounds of formula I using standard deprotection techniques (e.g. hydrogenation). The skilled person will appreciate that certain compounds of the invention may be regarded as protected derivatives of other compounds of the invention.

#### Medical and Pharmaceutical Use

Compounds of the invention may possess pharmacological activity as such. Compounds of the invention that may possess such activity include, but are not limited to, those with a free amidine functionality as part of the structural fragment B.

However, other compounds of formula I (including those that do not possess such a free amidine functionality) may not possess such activity, but may be administered parenterally or orally, and thereafter metabolised in the body to form compounds that are pharmacologically active (including, but not limited to, corresponding free amidine compounds). Such compounds (which also include compounds that may possess some pharmacological activity, but that activity is

appreciably lower than that of the active compounds to which they are metabolised to), may therefore be described as "prodrugs" of the active compounds.

Thus, the compounds of the invention are useful because they possess pharmacological activity, and/or are metabolised in the body following oral or parenteral administration to form compounds which possess pharmacological activity. The compounds of the invention are therefore indicated as pharmaceuticals.

According to a further aspect of the invention there is thus provided the compounds of the invention for use as pharmaceuticals.

In particular, the compounds of the invention are potent inhibitors of thrombin either as such and/or (e.g. in the case of prodrugs), are metabolised following administration to form potent inhibitors of thrombin, for example as demonstrated in the tests described below.

By "prodrug of a thrombin inhibitor", we include compounds that form a thrombin inhibitor, in an experimentally-detectable amount, and within a predetermined time (e.g. about 1 hour), following oral or parenteral administration.

The compounds of the invention are thus expected to be useful in those conditions where inhibition of thrombin is required.

The compounds of the invention are thus indicated in the treatment and/or prophylaxis of thrombosis and hypercoagulability in blood and tissues of animals including man.

It is known that hypercoagulability may lead to thrombo-embolic diseases. Conditions associated with hypercoagulability and thrombo-embolic diseases which may be mentioned include inherited or acquired activated protein C resistance, such as the factor V-mutation (factor V Leiden), and inherited or acquired deficiencies in antithrombin III, protein C, protein S, heparin cofactor II. Other conditions known to be associated with hypercoagulability and thrombo-embolic disease include circulating antiphospholipid antibodies (Lupus anticoagulant), homocysteinemia, heparin induced thrombocytopenia and defects in fibrinolysis. The compounds of the invention are thus indicated both in the therapeutic and/or prophylactic treatment of these conditions.

The compounds of the invention are further indicated in the treatment of conditions where there is an undesirable excess of thrombin without signs of hypercoagulability, for example in neurodegenerative diseases such as Alzheimer's disease.

Particular disease states which may be mentioned include the therapeutic and/or prophylactic treatment of venous thrombosis and pulmonary embolism, arterial thrombosis (eg in myocardial infarction, unstable angina, thrombosis-based stroke and peripheral arterial thrombosis) and systemic embolism usually from the atrium during arterial fibrillation or from the left ventricle after transmural myocardial infarction.

Moreover, the compounds of the invention are expected to have utility in prophylaxis of re-occlusion (ie thrombosis) after thrombolysis, percutaneous trans-luminal angioplasty (PTA) and coronary bypass operations; the prevention of re-thrombosis after microsurgery and vascular surgery in general.

Further indications include the therapeutic and/or prophylactic treatment of disseminated intravascular coagulation caused by bacteria, multiple trauma, intoxication or any other mechanism; anticoagulant treatment when blood is in contact with foreign surfaces in the body such as vascular grafts, vascular stents, vascular catheters, mechanical and biological prosthetic valves or any other medical device; and

anticoagulant treatment when blood is in contact with medical devices outside the body such as during cardiovascular surgery using a heart-lung machine or in haemodialysis.

In addition to its effects on the coagulation process, thrombin is known to activate a large number of cells (such as neutrophils, fibroblasts, endothelial cells and smooth muscle cells). Therefore, the compounds of the invention may also be useful for the therapeutic and/or prophylactic treatment of idiopathic and adult respiratory distress syndrome, pulmonary fibrosis following treatment with radiation or chemotherapy, septic shock, septicemia, inflammatory responses, which include, but are not limited to, edema, acute or chronic atherosclerosis such as coronary arterial disease, cerebral arterial disease, peripheral arterial disease, reperfusion damage, and restenosis after percutaneous transluminal angioplasty (PTA).

Compounds of the invention that inhibit trypsin and/or thrombin may also be useful in the treatment of pancreatitis.

According to a further aspect of the present invention, there is provided a method of treatment of a condition where inhibition of thrombin is required which method comprises administration of a therapeutically effective amount of a compound of the invention, or a pharmaceutically acceptable salt thereof, to a person suffering from, or susceptible to such a condition.

The compounds of the invention will normally be administered orally, intravenously, subcutaneously, buccally, rectally, dermally, nasally, tracheally, bronchially, by any other parenteral route or via inhalation, in the form of pharmaceutical preparations comprising active compound either as a free base, or a pharmaceutical acceptable non-toxic organic or inorganic acid addition salt, in a pharmaceutically acceptable dosage form. Depending upon the disorder and patient to be treated and the route of administration, the compositions may be administered at varying doses.

The compounds of the invention may also be combined and/or co-administered with any antithrombotic agent with a different mechanism of action, such as the antiplatelet agents acetylsalicylic acid, ticlopidine, clopidogrel, thromboxane receptor and/or synthetase inhibitors, fibrinogen receptor antagonists, prostacyclin mimetics and phosphodiesterase inhibitors and ADP-receptor ( $P_2T$ ) antagonists.

The compounds of the invention may further be combined and/or co-administered with thrombolytics such as tissue plasminogen activator (natural, recombinant or modified), streptokinase, urokinase, prourokinase, anisoylated plasminogen-streptokinase activator complex (APSAC), animal salivary gland plasminogen activators, and the like, in the treatment of thrombotic diseases, in particular myocardial infarction.

According to a further aspect of the invention there is thus provided a pharmaceutical formulation including a compound of the invention, in admixture with a pharmaceutically acceptable adjuvant, diluent or carrier.

Suitable daily doses of the compounds of the invention in therapeutical treatment of humans are about 0.001–100 mg/kg body weight at peroral administration and 0.001–50 mg/kg body weight at parenteral administration.

The compounds of the invention have the advantage that they may be, or may be metabolised to compounds that may be, more efficacious, be less toxic, be longer acting, have a broader range of activity, be more potent, produce fewer side effects, be more easily absorbed than, or that they may have other useful pharmacological, physical, or chemical, properties over, compounds known in the prior art.

### Test A

#### Determination of Thrombin Clotting Time (TT)

The inhibitor solution (25  $\mu$ L) was incubated with plasma (25  $\mu$ L) for three minutes. Human thrombin (T 6769; Sigma Chem. Co) in buffer solution, pH 7.4 (25  $\mu$ L) was then added and the clotting time measured in an automatic device (KC 10; Amelung).

The clotting time in seconds was plotted against the inhibitor concentration, and the  $IC_{50}TT$  was determined by interpolation.

$IC_{50}TT$  is the concentration of inhibitor in the test that doubles the thrombin clotting time for human plasma.

### Test B

#### Determination of Thrombin Inhibition With a Chromogenic, Robotic Assay

The thrombin inhibitor potency was measured with a chromogenic substrate method, in a Plato 3300 robotic microplate processor (Rosys AG, CH-8634 Hombrechtikon, Switzerland), using 96-well, half volume microtitre plates (Costar, Cambridge, Mass., USA; Cat No 3690). Stock solutions of test substance in DMSO (72  $\mu$ L), 1 mmol/L, were diluted serially 1:3 (24+48  $\mu$ L) with DMSO to obtain ten different concentrations, which were analysed as samples in the assay. 2  $\mu$ L of test sample was diluted with 124  $\mu$ L assay buffer, 12  $\mu$ L of chromogenic substrate solution (S-2366, Chromogenix, Mölndal, Sweden) in assay buffer and finally 12  $\mu$ L of  $\alpha$ -thrombin solution, (Human  $\alpha$ -thrombin, Sigma Chemical Co.) both in assay buffer, were added, and the samples mixed. The final assay concentrations were: test substance 0.00068–13.3  $\mu$ mol/L, S-2366 0.30 mmol/L,  $\alpha$ -thrombin 0.020 NIHU/mL. The linear absorbance increment during 40 minutes incubation at 37° C. was used for calculation of percentage inhibition for the test samples, as compared to blanks without inhibitor. The  $IC_{50}$ -robotic value, corresponding to the inhibitor concentration which caused 50% inhibition of the thrombin activity, was calculated from a log concentration vs. % inhibition curve.

### Test C

#### Determination of the Inhibition Constant $K_i$ for Human Thrombin

$K_i$ -determinations were made using a chromogenic substrate method, performed at 37° C. on a Cobas Bio centrifugal analyser (Roche, Basel, Switzerland). Residual enzyme activity after incubation of human  $\alpha$ -thrombin with various concentrations of test compound was determined at three different substrate concentrations, and was measured as the change in optical absorbance at 405 nm.

Test compound solutions (100  $\mu$ L; normally in buffer or saline containing BSA 10 g/L) were mixed with 200  $\mu$ L of human  $\alpha$ -thrombin (Sigma Chemical Co) in assay buffer (0.05 mol/L Tris-HCl pH 7.4, ionic strength 0.15 adjusted with NaCl) containing BSA (10 g/L), and analysed as samples in the Cobas Bio. A 60  $\mu$ L sample, together with 20  $\mu$ L of water, was added to 320  $\mu$ L of the substrate S-2238 (Chromogenix AB, Mölndal, Sweden) in assay buffer, and the absorbance change ( $\Delta A/min$ ) was monitored. The final concentrations of S-2238 were 16, 24 and 50  $\mu$ mol/L and of thrombin 0.125 NIH U/mL.

The steady state reaction rate was used to construct Dixon plots, i.e. diagrams of inhibitor concentration vs.  $1/(\Delta A/min)$ . For reversible, competitive inhibitors, the data points

for the different substrate concentrations typically form straight lines which intercept at  $x=-K_r$ .

#### Test D

##### Determination of Activated Partial Thromboplastin Time (APTT)

APTT was determined in pooled normal human citrated plasma with the reagent PTT Automated 5 manufactured by Stago. The inhibitors were added to the plasma (10  $\mu$ L inhibitor solution to 90  $\mu$ L plasma) and incubated with the APTT reagent for 3 minutes followed by the addition of 100  $\mu$ L of calcium chloride solution (0.025M) and APTT was determined in the mixture by use of the coagulation analyser KC10 (Amelung) according to the instructions of the reagent producer. The clotting time in seconds was plotted against the inhibitor concentration in plasma and the  $IC_{50}$ -APTT was determined by interpolation.

$IC_{50}$ -APTT is defined as the concentration of inhibitor in human plasma that doubled the Activated Partial Thromboplastin Time.

#### Test E

##### Determination of Thrombin Time Ex Vivo

The inhibition of thrombin after oral or parenteral administration of the compounds of formula I, dissolved in ethanol:Solutol™:water (5:5:90), were examined in conscious rats which, one or two days prior to the experiment, were equipped with a catheter for blood sampling from the carotid artery. On the experimental day blood samples were withdrawn at fixed times after the administration of the compound into plastic tubes containing 1 part sodium citrate solution (0.13 mol per L) and 9 parts of blood. The tubes were centrifuged to obtain platelet poor plasma. The plasma was used for determination of thrombin time as described below.

The citrated rat plasma, 100  $\mu$ L, was diluted with a saline solution, 0.9%, 100  $\mu$ L, and plasma coagulation was started by the addition of human thrombin (T 6769, Sigma Chem Co, USA) in a buffer solution, pH 7.4, 100  $\mu$ L. The clotting time was measured in an automatic device (KC 10, Amelung, Germany).

Where a "prodrug" compound of formula I was administered, concentrations of the appropriate active thrombin inhibitor of formula I (e.g. the free amidine or guanidine compound) in the rat plasma were estimated by the use of standard curves relating the thrombin time in the pooled citrated rat plasma to known concentrations of the corresponding "active" thrombin inhibitor dissolved in saline.

Based on the estimated plasma concentrations of the active thrombin inhibitor (which assumes that thrombin time prolongation is caused by the aforementioned compound) in the rat, the area under the curve after oral and/or parenteral administration of the corresponding prodrug compound of formula I was calculated (AUCpd) using the trapezoidal rule and extrapolation of data to infinity.

The bioavailability of the active thrombin inhibitor after oral or parenteral administration of the prodrug was calculated as below:

$$[(AUCpd/dose)/(AUC_{active, parenteral}/dose) \times 100]$$

where  $AUC_{active, parenteral}$  represents the AUC obtained after parenteral administration of the corresponding active thrombin inhibitor to conscious rats as described above.

#### Test F

##### Determination of Thrombin Time in Urine ex vivo

The amount of the "active" thrombin inhibitor that was excreted in urine after oral or parenteral administration of "prodrug" compounds of the invention, dissolved in ethanol:

Solutol™:water (5:5:90), was estimated by determination of the thrombin time in urine ex vivo (assuming that thrombin time prolongation is caused by the aforementioned compound).

Conscious rats were placed in metabolism cages, allowing separate collection of urine and faeces, for 24 hours following oral administration of compounds of the invention. The thrombin time was determined on the collected urine as described below.

Pooled normal citrated human plasma (100  $\mu$ L) was incubated with the concentrated rat urine, or saline dilutions thereof, for one minute. Plasma coagulation was then initiated by the administration of human thrombin (T 6769, Sigma Chem Company) in buffer solution (pH 7.4; 100  $\mu$ L). The clotting time was measured in an automatic device (KC 10; Amelung).

The concentrations of the active thrombin inhibitor in the rat urine were estimated by the use of standard curves relating the thrombin time in the pooled normal citrated human plasma to known concentrations of the aforementioned active thrombin inhibitor dissolved in concentrated rat urine (or saline dilutions thereof). By multiplying the total rat urine production over the 24 hour period with the estimated mean concentration of the aforementioned active inhibitor in the urine, the amount of the active inhibitor excreted in the urine (AMOUNTpd) could be calculated.

The bioavailability of the active thrombin inhibitor after oral or parenteral administration of the prodrug was calculated as below:

$$[(AMOUNTpd/dose)/(AMOUNT_{active, parenteral}/dose) \times 100]$$

where  $AMOUNT_{active, parenteral}$  represents the amount excreted in the urine after parenteral administration of the corresponding active thrombin inhibitor to conscious rats as described above.

#### Test G

##### Metabolic Activation of Prodrug Compounds In Vitro

Prodrug compounds of formula I were incubated at 37° C. with liver microsomes or 10 000 g (referring to the centrifuge speed) supernatant fractions (i.e. s9 fraction) prepared from human or rat liver homogenate. The total protein concentration in the incubations were 1 or 3 mg/mL dissolved in 0.05 mol/L TRIS buffer (pH 7.4), and with the cofactors NADH (2.5 mmol/L) and NADPH (0.8 mmol/L) present. The total volume of the incubate was 1.2 mL. The initial prodrug concentrations were 5 or 10  $\mu$ mol/L. Samples were collected from the incubate at regular intervals more than 60 minutes after the start of the incubations. Samples (25  $\mu$ L) from the incubate were mixed with an equal volume of human or rat plasma and an appropriate amount of thrombin, and the clotting time (i.e. thrombin time) was measured on a coagulometer (KC 10; Amelung). The amount of "active" thrombin inhibitor formed was estimated by the use of standard curves relating the thrombin time in pooled citrated human or rat plasma to known concentrations of the corresponding "active thrombin inhibitor".
